## 2 Universal Quantum Gates

Consider the  $n$ -ary controlled operation  $c^n-U$  defined by

$$c^n-U|i_1 \dots i_n\rangle = |i_1 \dots i_n\rangle \otimes \begin{cases} U|j\rangle & \text{if } i_1, \dots, i_n = 1, \\ |j\rangle & \text{otherwise.} \end{cases}$$

How can we implement a complicated operation such as  $c^n-U$  using simple gates such as T<sub>f</sub> and c- $U$ ? The idea is to introduce a certain number of *control qubits*, which are initially set to 0. Then, we can implement  $c^n-U$  as follows (the right part of the array resets the work qubits to 0):

In fact, we can build up the Toffoli gate Tf from the two-qubit gates  $c-V$ ,  $c-V^{-1}$  and  $c-M_{\rightarrow}$ , where

$$V = \sqrt{M_{\rightarrow}} = \frac{1}{2} \begin{pmatrix} 1+i & 1-i \\ 1-i & 1+i \end{pmatrix},$$

as follows:

To see this, note that the gate on the right maps  $|ijk\rangle$  to  $|ij\rangle \otimes |f(i,j,k)\rangle$ , where

$$|f(i,j,k)\rangle = \begin{cases} |k\rangle & \text{if } |ij\rangle = |00\rangle, \\ V^{-1}V|k\rangle = |k\rangle & \text{if } |ij\rangle = |01\rangle, \\ VV^{-1}|k\rangle = |k\rangle & \text{if } |ij\rangle = |10\rangle, \\ VV|k\rangle = |k \oplus 1\rangle & \text{if } |ij\rangle = |11\rangle \end{cases}$$

$$= |ij \oplus k\rangle.$$

**Lemma 2.1.** Tf is computable by a QGA over  $\{H, c-M_{\rightarrow}, S, T, T^{-1}\}$  (see Figure 2.1).

*Proof.* By calculation.

Q.E.D.

The general question here is which gates are sufficient for building arbitrary unitary transformations. We will show that a QGA can be approximated arbitrarily well by a QGA that consists of Hadamard,  $cNOT$  and T gates only. More precisely, we will show that

- (1) every unitary transformation  $U$  can be written as a product  $U = U_m \dots U_1$  of unitary operators  $U_i$  that operate nontrivially only on a two-dimensional subspace of  $H_{2^n}$  (generated by two vectors of the standard basis).

Figure 2.1. An implementation of the Toffoli gate over  $\{H, c-M_{\rightarrow}, S, T, T^{-1}\}$ .

*Proof (Sketch).* Let  $V$  be the nontrivial, unitary  $(2 \times 2)$ -submatrix of  $U$ .  $V$  can be viewed as a 1-qubit gate. Recall that, for each  $n$ , the operation  $c^n$ - $V$  can be implemented using  $Tf$  (which can be built from  $CNOT$  and single qubit gates) and  $c$ - $V$ . The gate  $c$ - $V$ , on the other hand, can be implemented using  $CNOT$  and single qubit operations (see Nielsen & Chuang, *Quantum Computation and Quantum Information*, Section 4.3).

Fix a sequence  $|z_1\rangle, \dots, |z_m\rangle$  of basis vectors such that  $|z_1\rangle = |x\rangle$ ,  $|z_m\rangle = |y\rangle$ , and  $|z_i\rangle$  differs from  $|z_{i+1}\rangle$  on precisely one qubit. The idea is to implement  $U$  as a product  $U = P_1 \cdots P_{m-1} (c^*-V) P_{m-1} \cdots P_1$ . The matrix  $P_i$  maps  $|z_i\rangle$  to  $|z_{i+1}\rangle$  and vice versa, and  $c^*$ - $V$  is the operation of  $V$  on the qubit that distinguishes  $|z_{m-1}\rangle$  and  $|z_m\rangle$ , controlled by all other qubits. Note that  $P_{m-1} \cdots P_1$  maps  $|x\rangle$  to  $|y\rangle$ , and  $P_1 \cdots P_{m-1}$  maps  $|y\rangle$  back to  $|x\rangle$ . As we have seen,  $c^*$ - $V$  and each  $P_i$  can be implemented using  $CNOT$  and 1-qubit gates. Q.E.D.

Finally, we can discuss (3), the reduction of arbitrary 1-qubit gates to  $H$  and  $T$ . Note that there exist uncountably many unitary transformations  $U : H_{2^n} \rightarrow H_{2^n}$ , but from a finite (or even countably infinite) set of gates, we can only compose countably many QGAs. Hence, there is no way of representing every 1-qubit gate *exactly* using a fixed finite set of gates. However, an *approximation* is possible! For two unitary transformations  $U$  and  $V$ , we define

$$E(U, V) := \max_{\|\psi\rangle=1} \|(U - V)|\psi\rangle\|.$$

**Definition 2.6.** A set  $\Omega$  of quantum gates is *universal* if for any QGA  $U$  and every  $\varepsilon > 0$ , there is a QGA  $V$  consisting only of gates from  $\Omega$  such that  $E(U, V) \leq \varepsilon$ .

**Theorem 2.7 (Solvay-Kitaev).** For every QGA  $U$  consisting of  $m$   $CNOT$  or 1-qubit gates and for every  $\varepsilon > 0$ , there exists a QGA  $V$  of size  $O(m \cdot \log^c \frac{m}{\varepsilon})$ ,  $c \approx 2$ , consisting of  $CNOT$ ,  $H$  and  $T$  gates only such that  $E(U, V) \leq \varepsilon$ .
